Parallel Pairwise Operations on Data Stored in DNA: Sorting, Shifting and Searching

Tonglin Chen, Arnav Solanki, Marc Riedel

$\pi$

## CS 101: Sorting, Searching, Shifting

## Sorting

Applications: string processing, genomics, combinatorics, ... Binary data: majority operations, thresholding operations in neural networks.

Searching
Applications: genomics, data mining, .. Binary data: pattern matching, ..

## Shifting

Applications: image processing, ... Binary data: multiplying/dividing, scaling, activation functions in neural networks.

## Agenda

$>$ Background

- DNA Storage via Nicks.
- "In-Memory" Computation: SIMD operations.
$>$ Technical Details
- Encoding binary data.
- Transforming bits, pairwise, in parallel.
> Applications
- Parallel Binary Sorting
- Parallel Searching
- Parallel Shifting (omitted)
$>$ Summary

## Data Storage: Conventional Approach

Nucleotides: $\{A, C, T, G\}$
DNA: string of nucleotides

## Our storage modality: "Nicks"

## Gene editing with CRISPR/Cas9 or PfAgo

Simplest form: a cut represents a 1; absence of a cut a 0 .

॥!!!!!
"!ннин
 fifilifis t

## Our storage modality: "Nicks"

Gene editing with CRISPR/Cas9 or PfAgo
Encode data by a pattern of cuts, followed by heating.

## Parallelism with Nick-Based Displacement

- Single-instruction applied to multiple data (SIMD).
- A single common "instruction" can initiate a sequence of computation on many (currently 10s, in the future millions) of "registers".
- Instruction is a single synthesized strand. Registers are copies of identical DNA nicked to encode different values (so a vector or a matrix.)

| 0 | 1 | 1 | 0 | 1 | 1 |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 1 | 1 | 1 | 1 | 1 | 1 |
| 0 | 0 | 0 | 0 | 0 | 0 |
| 0 | 1 | 0 | 0 | 1 | 0 |
| 0 | 0 | 1 | 0 | 0 | 1 |
| 1 | 1 | 0 | 1 | 1 | 0 |
| 0 | 1 | 0 | 0 | 1 | 0 |
| 0 | 0 | 1 | 0 | 0 | 1 |

## Parallelism with Nick-Based Displacement

Two levels of parallelism:

1. Bit-level Parallelism: instructions applied to all bits in array at once.
2. Data-level Parallelism: same instructions can be applied to different data in different arrays at once.

## Parallelism with Nick-Based Displacement

Two levels of parallelism:

1. Bit-level Parallelism: instructions applied to all bits in array at once.
2. Data-level Parallelism: same instructions can be applied to different data in different arrays at once.

## Encoding

$\rightarrow$ How do we represent bits in DNA cells?
Bit 0

$\rightarrow$ Example: register with 5 cells (1,1,0,0,1)

## Example: From $(1,0)$ to $(0,1)$

Original: we have pair ( 1,0 ) here.

## Example: From $(1,0)$ to $(0,1)$

Step 1: Add strand S1 that covers domains 6712 3. Strands (6 7) and (2 3) are displaced

## Example: From $(1,0)$ to $(0,1)$

Step 1: Add strand S1 that covers domains 6712 3. Strands (6 7) and (2 3) are displaced

## Example: From $(1,0)$ to $(0,1)$

Step 2: Extract S1 with S1* (complementary strand). S1 and S1* forms a waste complex.

## Example: From $(1,0)$ to $(0,1)$

Step 2: Extract S1 with S1* (complementary strand). S1 and S1* forms a waste complex.

## Example: From $(1,0)$ to $(0,1)$

Step 3: "protect" second cell (in this case bit 0). Then we can focus on rewriting first cell.

## Example: From $(1,0)$ to $(0,1)$

Step 4: Cover domains 2-7.

Instruction

## Example: From $(1,0)$ to $(0,1)$

## Step 4: Cover domains 2-7.

Waste

## Example: From $(1,0)$ to $(0,1)$

Step 5: remove cover strand.

## Example: From $(1,0)$ to $(0,1)$

Step 5: remove cover strand.

## Example: From $(1,0)$ to $(0,1)$

Step 6: write bit 0

Instruction

## Example: From $(1,0)$ to $(0,1)$

Step 6: write bit o.

Waste

## Example: From $(1,0)$ to $(0,1)$

Step 7: release the protection on the second cell.

## Example: From $(1,0)$ to $(0,1)$

Step 7: release the protection on second cell.

Waste $\quad$ Sp 23

## Example: From $(1,0)$ to $(0,1)$

Step 8: cover domains 2-7.

## Example: From $(1,0)$ to $(0,1)$

Step 8: cover domains 2-7.

Waste

## Example: From $(1,0)$ to $(0,1)$

Step 9: release the cover.

Instruction

## Example: From $(1,0)$ to $(0,1)$

Step 9: release the cover

Waste

## Example: From $(1,0)$ to $(0,1)$

Step 10: write bit 1.

Instruction

## Example: From $(1,0)$ to $(0,1)$

Step 10: write bit 1.

Waste

## Pairwise Parallel Operations

$\rightarrow$ Common instructions that operate on a specific pair of bits in a register.

- 4 possible pairs - ( 0,0 ), ( 0,1 ), ( 1,0 ), and ( 1,1 ).
- Example 1 - identify all cells containing o that are followed by cells containing 1 identify ( 0,1 )
- Example 2 - convert all pairs (1,0) into (1,1)
- Must be careful about using random access memory -- are the domain sequences unique or not? Unique sequence allows for specific pair targeting, but requires more instruction strands

## Binary Bubble Sorting

$\rightarrow$ One of the most basic computing tasks: rearrange a list of items into ascending/descending order.
$\rightarrow$ Serial sorting algorithms take approximately $n \log _{2} n$ steps to sort $n$ items.
$\rightarrow$ Parallel sorting algorithms take approximately $n$ parallel steps to sort $n$ items.

## Binary Bubble Sorting

## Repeat n times

For every pair of bits (overlapping)
If pair is ( 1,0 ), swap to $(0,1)$

## Binary Bubble Sorting

Starting list

Ins 2: Detaching S1 from non $(1,0)$ pairs

## Other Pairwise operations - (1,1) and (0,0)

Wash away waste

Wash away waste

## Other Pairwise operations - (1,1) and (0,0)

Ins 3: Identifying pair $(0,0)$

## Other Pairwise operations - (1,1) and (0,0)

## Other Pairwise operations - (0,1)

Original: $(0,1)$

## Parallel Searching - Example 1

Query $=1101$, String $=10101010110110100011110101000100$

First level: $a=00, b=01, c=10, d=11$

## Parallel Searching - Example 1

Query $=1101$, String $=10101010110110100011110101000100$

First level: $a=00, b=01, c=10, d=11$
Second level: $e=c c, f=d b, g=a d, h=b a$

## Parallel Searching - Example 1

Query $=1101$, String $=10101010110110100011110101000100$

First level: $a=00, b=01, c=10, d=11$
Second level: $e=c c, f=d b, g=a d, h=b a$
Note that query $=1101=\mathrm{db}=\mathrm{f}$.

## Parallel Searching - Example 2

Substring does not always start on multiples of query length! Query $=1011$, String $=10101010110110100011110101000100$ Solution: Create copies, each with 0 to $\mathrm{N}-1$ bits truncated at the start

First level: $a=00, b=01, c=10, d=11$

## Parallel Searching - Example 2

Substring does not always start on multiples of query length! Query $=1011$, String $=10101010110110100011110101000100$ Solution: Create copies, each with 0 to $\mathrm{N}-1$ bits truncated at the start

First level: $a=00, b=01, c=10, d=11$
Second level: $e=c c, f=d b, g=a d, h=b a, i=c d, j=b c, k=c a, l=d d, m=b b, n=a b$

## Parallel Searching - Example 2

Substring does not always start on multiples of query length! Query $=1011$, String $=10101010110110100011110101000100$ Solution: Create copies, each with 0 to $\mathrm{N}-1$ bits truncated at the start

First level: $a=00, b=01, c=10, d=11$
Second level: $e=c c, f=d b, g=a d, h=b a, i=c d, j=b c, k=c a, l=d d, m=b b, n=a b$ Found the query with i

## Parallel Searching - Example in DNA

(a) Initial Sequence 1011

(b) Identifier $A_{2}$ captures first pair $10, A_{3}$ captures second pair 11

(c) covering the domain 1 between the two bit pairs

(d) Rewrite the content in the pair so that new identifiers are close to the middle

(e) Two identifier strands replaced by a single identifier if there is a perfect match

## Complexity of Search

N : length of query string.
M : length data string.
$\rightarrow$ Number of levels: O(logN)
$\rightarrow$ Number of sequential steps: O(N)

- At level $i$ :
- at most $\frac{n}{2^{i}}$ pairs of symbols
- at most $2^{2^{i}}$ distinct pairs
- first two levels requires fewer steps

## Nick-based In-Memory Computing

Objectives:

- Leverage the high-density of storage with effective computation.
- Perform "computation in memory" to reduce I/O operations.
- Integrate storage with data-intensive algorithms, such as machine learning.

## Motivation:

Query: Does

- Techniques such as data aggregation and could reduce the I/O requirements.
- The paradigm might be most effective for applications that generate large volumes of static data.
- Perform SQL-like, Database-like queries on large volumes of data.
Answer: Yes or No
